Sounds like problems with your ILP. I think it gave you issues in the past too?

In the end 1% may not make any difference to your final ranking as you are 1.5% behind the next place.

Thanks, but yes I can see all the seeds and the log of my program. So I know which seeds I failed.
Anyway, I would say lesson learned but apparently I never learn =)

And to answer your question, it's the first time I use my ILP in a competition (and maybe last...), So no never had an issue before.

Where do you see I am 1.5% behind the next place? I see a very small difference between [yowa](#) and myself, anyway, it does not matter, the failures are real, so I get the ranking I deserve for my sloppiness!

Similar solution with two phases

1. Predicting original attack and defense strengths using SA that minimizes the product of probabilities of each player ending up with given number of scored and conceded goals. For given strengths we have the probabilities of each score happening (very similar to [eulerscheZahl](#)'s code except the last part where I have separate probability for each goal count instead)
2. We haven't used the points information yet. We can refine initial probabilities using the Bayes theorem with dynamic programming like described in [ika](#)'s post. To fit $n=50$ in time/memory I had to cut out the most important $16 \times 16 \times 50$ sub-array on each step. The last improvements were to repeat this step once

again (which gave around +0.3% locally), taking the weighted average of probabilities ($0.2 \cdot \text{old} + 0.8 \cdot \text{new}$) and in the end return the score that maximizes $2 \cdot \text{score} + 1 \cdot \text{outcome}$ (another +0.3%), not the most likely one.
